

• **Haloperidol**

- Oral tablet: 0.5 mg, 1 mg, 2 mg, 5 mg, 10 mg, 20 mg
- Oral solution: 2 mg/mL
- Intramuscular injection (short-acting): 5 mg/mL

• **Haloperidol decanoate**

- Intramuscular injection oil (long-acting): 50 mg/mL, 100 mg/mL

• **Haldol® decanoate**

- Intramuscular injection oil (long-acting): 50 mg/mL, 100 mg/mL

If you or someone you know is in crisis, please call 911 and/or the toll-free National Suicide Prevention Lifeline at 800-273-TALK (8255) to speak with a trained crisis counselor 24/7. A help line and other resources are also available through the National Alliance on Mental Illness at nami.org.

What is haloperidol and what does it treat?

Haloperidol is a medication that works in the brain to treat schizophrenia. It is also known as a first generation antipsychotic (FGA) or typical antipsychotic. Haloperidol rebalances dopamine to improve thinking, mood, and behavior.

Symptoms of schizophrenia include:

- Hallucinations – imagined voices or images that seem real
- Delusions - beliefs that are not true (e.g., other people are reading your thoughts)
- Disorganized thinking or trouble organizing your thoughts and making sense
- Little desire to be around other people
- Trouble speaking clearly
- Lack of motivation

Haloperidol may help some or all of these symptoms.

Haloperidol is also FDA approved for Tourette’s syndrome as well as hyperactive behavior or severe behavioral problems in children that do not respond to therapy or other medications.

Haloperidol may also be helpful when prescribed “off-label” for other mental health conditions. “Off-label” means that it has not been approved by the Food and Drug Administration for this condition. Your mental health provider should justify his or her thinking in recommending an “off-label” treatment. They should be clear about the limits of the research around that medication and if there are any other options.

What is the most important information I should know about haloperidol?

Schizophrenia requires long-term treatment. Do not stop taking haloperidol, even when you feel better.

With input from you, your health care provider will assess how long you will need to take the medication.

Missing doses of haloperidol may increase your risk for a relapse in your symptoms.

Do not stop taking haloperidol or change your dose without talking with your health care provider first.

For haloperidol to work properly, it should be taken every day as ordered by your health care provider.

All FDA warnings are at the end of this fact sheet. Please consult them before taking this medication.

Are there specific concerns about haloperidol and pregnancy?

If you are planning on becoming pregnant, notify your health care provider to best manage your medications. People living with schizophrenia who wish to become pregnant face important decisions. This is a complex decision since untreated schizophrenia has risks to the fetus, as well as the mother. It is important to discuss the risks and benefits of treatment with your doctor and caregivers.

Antipsychotic use during the third trimester of pregnancy has a risk for abnormal muscle movements (extrapyramidal symptoms [EPS]) and/or withdrawal symptoms in newborns following delivery. Symptoms in the newborn may include agitation, feeding disorder, hypertonia, hypotonia, respiratory distress, somnolence, and tremor; these effects may be self-limiting or require hospitalization.

Caution is advised with breastfeeding since haloperidol does pass into breast milk.

What should I discuss with my health care provider before taking haloperidol?

- Symptoms of your condition that bother you the most
- If you have thoughts of suicide or harming yourself
- Medications you have taken in the past for your condition, whether they were effective or caused any adverse effects
- If you ever had muscle stiffness, shaking, tardive dyskinesia, neuroleptic malignant syndrome, or weight gain caused by a medication
- If you experience side effects from your medications, discuss them with your provider. Some side effects may pass with time, but others may require changes in the medication.
- Any psychiatric or medical problems you have, such as heart rhythm problems, long QT syndrome, heart attacks, diabetes, high cholesterol, or seizures
- If you have a family history of diabetes or heart disease
- All other medications you are currently taking (including over the counter products, herbal and nutritional supplements) and any medication allergies you have
- Other non-medication treatment you are receiving, such as talk therapy or substance abuse treatment. Your provider can explain how these different treatments work with the medication.
- If you are pregnant, plan to become pregnant, or are breastfeeding
- If you smoke, drink alcohol, or use illegal drugs

How should I take haloperidol?

Haloperidol tablets and solution are usually taken 1 or 2 times per day with or without food.

Typically patients begin at a low dose of medication and the dose is increased slowly over several weeks.

The dose of the oral medication usually ranges from 5 mg to 20 mg. The dose of the long-acting injection is 25 mg to 200 mg. Only your health care provider can determine the correct dose for you.

Haloperidol oral solution should be measured with a dosing spoon or oral syringe, which you can get from your pharmacy if one is not provided with the product.

Use a calendar, pillbox, alarm clock, or cell phone alert to help you remember to take your medication. You may also ask a family member or friend to remind you or check in with you to be sure you are taking your medication.

The long-acting injection form of haloperidol is administered every 3 to 4 weeks. Your health care provider will administer these injections.

What happens if I miss a dose of haloperidol?

If you miss a dose of haloperidol, take it as soon as you remember, unless it is closer to the time of your next dose. Discuss this with your health care provider. Do not double your next dose or take more than what is prescribed.

What should I avoid while taking haloperidol?

Avoid drinking alcohol or using illegal drugs while you are taking haloperidol. They may decrease the benefits (e.g., worsen your confusion) and increase adverse effects (e.g., sedation) of the medication.

What happens if I overdose with haloperidol?

If an overdose occurs call your doctor or 911. You may need urgent medical care. You may also contact the poison control center at 1-800-222-1222.

A specific treatment to reverse the effects of haloperidol does not exist.

What are the possible side effects of ziprasidone?

Common side effects

Rapid heartbeat, constipation, blurry vision, dry mouth, drop in blood pressure upon standing, extrapyramidal symptoms

Feeling drowsy, dizzy, or restless

Patients receiving haloperidol decanoate long-acting injection may notice some pain at the site of the injection. This pain should resolve after a few days.

Rare/serious side effects

Haloperidol may increase the blood levels of a hormone called prolactin. Side effects of increased prolactin levels include females losing their period, production of breast milk and males losing their sex drive or possibly experiencing erectile problems. Long term (months or years) elevated prolactin levels can lead to osteoporosis or increased risk of bone fractures.

Some people may develop muscle related side effects while taking haloperidol. The technical terms for these are “extrapyramidal symptoms” (EPS) and “tardive dyskinesia” (TD). Symptoms of EPS include restlessness, tremor, and stiffness. TD symptoms include slow or jerky movements that one cannot control, often starting in the mouth with tongue rolling or chewing movements.

Temperature regulation: Impaired core body temperature regulation may occur; caution with strenuous exercise, heat exposure, and dehydration.

All antipsychotics have been associated with the risk of sudden cardiac death due to an arrhythmia (irregular heart beat). To minimize this risk, antipsychotic medications should be used in the smallest effective dose when the benefits outweigh the risks. Your doctor may order an EKG to monitor for irregular heartbeat.

Neuroleptic malignant syndrome is a rare, life threatening adverse effect of antipsychotics which occurs in <1% of patients. Symptoms include confusion, fever, extreme muscle stiffness, and sweating. If any of these symptoms occur, contact your health care provider immediately.

All antipsychotics can cause sedation, dizziness, or orthostatic hypotension (a drop in blood pressure when standing up from sitting or lying down). These side effects may lead to falls which could cause bone fractures or other injuries. This risk is higher for people with conditions or other medications that could worsen these effects. If falls or any of these symptoms occur, contact your health care provider.

Are there any risks for taking haloperidol for long periods of time?

Tardive dyskinesia (TD) is a side effect that develops with prolonged use of antipsychotics. If you develop symptoms of TD, such as grimacing, sucking, and smacking of lips, or other movements that you cannot control, contact your health care provider immediately. All patients taking either first or second generation antipsychotics should have an Abnormal Involuntary Movement Scale (AIMS) completed regularly by their health care provider to monitor for TD.

What other medications may interact with haloperidol?

Haloperidol may block the effects of agents used to treat Parkinson's disease such as levodopa/carbidopa (Sinemet®), bromocriptine, pramipexole (Mirapex®), ropinirole (Requip®), and others.

Haloperidol may lower your blood pressure. Medications used to lower blood pressure may increase this effect and increase your risk of falling. Propranolol (Inderal®) is an example of this type of medication.

The following medications may increase the risk of heart problems when used with haloperidol:

- Antipsychotics including chlorpromazine (Thorazine®), thioridazine (Mellaril®), iloperidone (Fanapt®), paliperidone (Invega®), pimozide (Orap®), quetiapine (Seroquel®), and ziprasidone (Geodon®).
- Antiarrhythmics (heart rhythm medications) including procainamide, quinidine, amiodarone (Cordarone®), dronedarone (Multaq®), and sotalol (Betapace®).

Metoclopramide (Reglan®) may increase the risk of EPS or TD when used in combination with haloperidol.

The following medications may increase the levels and effects of haloperidol: bupropion (Wellbutrin®), fluoxetine (Prozac®), fluvoxamine (Luvox®), ketoconazole (Nizoral®), venlafaxine (Effexor®), and paroxetine (Paxil®).

The following medications may decrease the levels and effects of haloperidol: carbamazepine (Tegretol®, Equatro®), phenytoin (Dilantin®), phenobarbital, and rifampin (Rifadin®).

How long does it take for haloperidol to work?

It is very important to tell your doctor how you feel things are going during the first few weeks after you start taking haloperidol. It will probably take several weeks to see big enough changes in your symptoms to decide if haloperidol is the right medication for you.

Antipsychotic treatment is generally needed lifelong for persons with schizophrenia. Your doctor can best discuss the duration of treatment you need based on your symptoms and illness.

- Hallucinations, disorganized thinking, and delusions may improve in the first 1-2 weeks
- Sometimes these symptoms do not completely go away
- Motivation and desire to be around other people can take at least 1-2 weeks to improve
- Symptoms continue to get better the longer you take haloperidol
- It may take 2-3 months before you get the full benefit of haloperidol

Summary of Black Box Warnings

Increased Mortality in Elderly Patients with Dementia Related Psychosis

- Both first generation (typical) and second generation (atypical) antipsychotics are associated with an increased risk of mortality in elderly patients when used for dementia related psychosis.
- Although there were multiple causes of death in studies, most deaths appeared to be due to cardiovascular causes (e.g., sudden cardiac death) or infection (e.g., pneumonia).
- Antipsychotics are not indicated for the treatment of dementia-related psychosis.
